

# Psychological biases and barriers to climate change engagement:

## A guide for educators

A few different theories of psychology, mainly in the form of cognitive biases, offer explanations for human inaction on climate change mitigation, on the individual and collective scale.

These shortcuts in thinking originally evolved to ensure our ancestors' survival by allowing them to think quickly and filter out unnecessary information to avert danger. We didn't want to waste energy thinking and worrying about things that weren't an immediate physiological need. Rather, it was an evolutionary advantage to be on the look-out for predators, to gather resources and be accepted by tribe. However, when we act on the assumptions and instincts in this 'fast' mode of thinking (Kahneman, 2011), we can struggle to make rational, balanced decisions based on a fair assessment of the information available. What once kept us safe, may now be working against us.

Consider the psychological processes that would have to happen before an individual is ready to take action on climate change, defined in this guide as:

1. Understanding climate change
2. Perceiving it as a threat
3. Continued attention to it
4. Regulating overwhelm

There are 'thinking traps' or psychological biases that affect human thinking at each stage.

# Thinking traps: 1. (not) Understanding the climate problem

The scale and reach of the interacting causes and impacts of climate change make it complex, overwhelming and hard to fully grasp. As Time Magazine puts it: 'Climate is Everything'.

It is an intangible 'Hyperobject' that 'massively out scales us' (Morton, 2013). It can be hard to know where to begin. Most people perhaps have more salient things to think about, such as meeting a deadline, or how to pay the rent.

Even if you do choose to engage with the topic, finding the right information is not straightforward when presented with so many different sources.

We tend to seek out comforting news (optimism bias), or articles that agree with what we already believe (confirmation bias).

This can result in the 'echo chamber' phenomenon, with social media algorithms serving up more of what we seem to be interested in.

The algorithms also tend to expose us to attention grabbing news, even if it is fake. Many trusted influencers may unwittingly share or re-post something without even knowing it is 'fake', giving it more traction.

The growing phenomenon of artificial intelligence (AI) generated 'deep fakes', (where voices and faces can be cloned, creating a very convincing video) poses an even greater challenge to spot.

Together, the combination of echo chambers and a mistrust of those outside the 'chamber', high uncertainty and complexity can breed conspiracy narratives. While conspiracy theories can offer a soothingly simple solution to a complex problem, they are known to reduce intentions to act on climate (Jolley, 2013).

## HOW TO SPOT FAKE NEWS

- CONSIDER THE SOURCE**  
Click away from the story to investigate the site, its mission and its contact info.
- READ BEYOND**  
Headlines can be outrageous in an effort to get clicks. What's the whole story?
- CHECK THE AUTHOR**  
Do a quick search on the author. Are they credible? Are they real?
- SUPPORTING SOURCES?**  
Click on those links. Determine if the info given actually supports the story.
- CHECK THE DATE**  
Reposting old news stories doesn't mean they're relevant to current events.
- IS IT A JOKE?**  
If it is too outlandish, it might be satire. Research the site and author to be sure.
- CHECK YOUR BIASES**  
Consider if your own beliefs could affect your judgement.
- ASK THE EXPERTS**  
Ask a librarian, or consult a fact-checking site.

IFLA  
International Federation of Library Associations and Institutions

Encouragingly, the Department for Education (DfE, 2022) is now recognising the imperative to educate children on climate change.

## 1. Recommendations

Teach:

- The science of climate change in reference to the Intergovernmental Panel on Climate Change (IPCC)
- Geopolitical & economics of climate change (e.g. carbon credits, CoP mechanisms)
- Theories of social change and past successes (e.g. ozone layer)
- Human responses to climate change - our psychology models that 'gather' the biases may be helpful

e.g. Per Espen Stoknes 5 D's model is a clear model of defences, which offer 5 solutions

Practice skills:

- Of checking facts and information sources, reasoning and critical thinking
- Of oracy and debate to weigh up both sides of an argument

# Thinking traps: 2. (not) Perceiving climate

as a  
problem

Even those that understand climate change can still struggle to perceive it as an existential threat. That is because, according to Harvard psychologist Dan Gilbert our brains have evolved to respond to threats that have the following features:

- **Personal** - a threat from other humans e.g. a pickpocket.
- **Abrupt** - sudden changes e.g. a bomb.
- **Immoral** - things that are indecent or repulsive e.g. violence against a person
- **Now** - happening immediately or could happen soon e.g. losing your job.

So, while the threat of burglaries or terrorism taps into all four features (and therefore affects policy and behaviour), climate change is for many people, a somewhat distant, unfolding problem, not involving any particular perpetrator or amoral 'enemy'. We struggle to *feel* alarmed at reports of '400 parts per

## Climate Changes Endanger World's Food Output

By HAROLD M. SCHNECK Jr.  
Bad weather this summer and the threat of more of it to come have ominously reared every estimate of the world food situation.

It is a threat the world may have to face more often in the years ahead. Many weather scientists expect greater variability in the earth's weather and, consequently, greater risk of local disasters in places where conditions of recent years have become accepted as the "normal" weather.

This is another in a series of articles which will appear from time to time, examining the world food situation.

Severe weather changes, ranging from floods to drought, have struck many of the world's major agricultural areas so far this year. Climate experts say that even greater variability of weather can be expected in years to come, bringing changes to arable areas that have adjusted to past patterns, thus threatening future output.

In the United States, the world's most important food producer, a severe drought that began last fall in the Southwest has spread northward and westward, and may have potentially serious effects in the Corn Belt. There have also been reports that spring wheat in the United States has been badly hurt by hot, dry weather. Earlier this year, there had been hopes of bumper crops in North America and elsewhere. But the weather's adverse impact has crumpled some of these hopes.

Which one gets your attention?

Which has greater consequences?

However, the impacts of flooding, drought and wildfires are becoming 'personal', 'abrupt' and 'now' for increasing numbers of people. Climate is now being recognised as an existential threat.

The historic 'cover up' of climate impacts by oil giants is increasingly recognised as immoral (Wallis-Wells, 2019). Activists and campaigners perhaps have been successful in highlighting climate change as a threat because they have helped highlight the 'immorality' of some people's or organisations' unsustainable actions.

Another barrier we have with regard to threat perception is our difficulty in thinking mathematically (Slovic, 2020). A 2° level of global warming does not mean that your 20° days will just become 22°. The seemingly small degrees of warming refer to global average temperatures and perhaps hide the extremes of variability

Dr Louise Edgington

[www.ClimatEdPsych.com](http://www.ClimatEdPsych.com)

and unpredictability across the globe, as well as ignoring the impacts secondary consequences (e.g. disease outbreaks, crop failure).

**We also have difficulty** with an exponential curve. Biases such as 'anchoring' and the availability heuristic (where people are swayed by recently seen and readily available figures) mean that we automatically tend to make linear projections of change.

In other words, we look at the last five years' temperature rise and assume that the next five years will be similar. This is not the case, unless, perhaps emissions had stayed to stay at 2000 levels (orange line in Image - source: Intergovernmental Panel on Climate Change (IPCC) WG1 AR-4).

The rate of change in temperature is actually accelerating due to interacting feedback systems or that reinforce each other (e.g. warmer oceans hold less CO<sub>2</sub> which causes more warming).

However, there is a danger that presenting the full severity of future scenarios can actually cause many people to become more sceptical (Feinberg & Willer, 2010), particularly when combined with a perceived lack of control.

**The framing effect** shows that people are more likely to change their behaviour when the *benefits* of action are highlighted (e.g. if we switch to electric vehicles, you'll save money on fuel, reduce emissions and save X number of lives), rather than the risks of inaction (e.g. if we do nothing, humans will become extinct). There is a balance to be struck between messages that raise alarm, without evoking the mechanisms of denial and fatalism that can lead to inaction.

## 2. Recommendations

### Balance and truth:

- When teaching or talking with children about climate change risks, we have a responsibility not to 'sugar-coat' the climate situation, but to illustrate how climate may soon become an imminent and personal threat to all, whilst presenting a hopeful alternative to inspire agency and motivate change.
- Present 2/3 solutions for every difficult fact. e.g. <https://drawdown.org/climate-solutions-101>

### Solution focussed futures:

- 'The Future we Choose' (Figueres & Rivett Carnac, 2020) is an article which explores two alternative futures in 2050, neatly balancing out the severity of the situation, while presenting a path forward.
- Media within the genre of 'solar punk' offers a utopian vision of a sustainable future.

# Thinking traps: 3. (dis) Continued attention to climate

**Even** if we understand climate change to be a real threat, there are other biases that result in us tending to ignore climate change and carry on as normal.

So even though we are no longer in 'cognitive' denial, we are in denial through our actions - carrying on with our more 'convenient lives'. It's natural for all of us to slip into convenience and familiarity from time to time, but the aim is to maintain awareness of progress towards sustainability.

Here are a selection of the most common biases, from Gifford (2011) and Kahneman (2011):

### Technosalvation

The belief that technology or AI alone (e.g. carbon capture options) will save us

### Bystander effect

In a large group, we tend to assume that someone else will sort a problem or situation (e.g. governments)

### Inconsistent world views

Belief in the power of free-market capitalism or anthropocentrism (that humans are the central being in the universe) isn't compatible with sustainable behaviours

### Sunk Costs Fallacy

If time or money has been invested in something (e.g. fossil fuel infrastructure), we tend to hang onto cling to the suboptimal investment

www.ClimatEdPsych.com

### Social comparison effect

We are less likely to act if we see others not acting and perceived inequality. e.g. using the justifications 'everyone else is eating meat!'

ANNE-MARIE BONNEAU

### 3. Recommendations

#### Embrace imperfection:

- Don't judge yourself or others when you notice a denial mechanisms at play.
- As an educator, model manageable and consistent behaviour changes & actions.
- Show understanding and curiosity for family belief/ biases - this can lead to a productive conversation

#### Staying vigilant:

- Model staying 'aware' of these mechanisms of denial and share how they may have shown up in your life.
- Look at Gifford's Dragons - a self-inventory of 33 biases
- Consider with pupils - what biases are at play in your school?

# Thinking traps: 4. (not) regulating overwhelm

Apocalyptic or fatalistic thinking is a shortcut that people can take when faced with the enormity of climate change. This can easily lead to inaction and feeling overwhelmed.

It's also not helpful to spread such messages, as it may cause other people to 'give up'.

While some threats may be real, thoughts about what could happen are not *actually* fact.

The anxiety may be worse than it needs to be due to some of the following thinking errors, reinforcing negative thinking patterns:

## Climate Change Thinking Traps

### Saviour Complex

- e.g. "I've got to convince them"
- Overassuming responsibility
  - Can lead to burn out.
- You don't have to save the world

### Selective attending & doomscrolling

- e.g. "governments are doing nothing"
- Excessive 'bad' news consumption
  - Linked to poor mental health
  - It can warp your worldview

### Catastrophising & Fatalism

- e.g. "what's the point, we're all doomed"
- Can lead to 'giving up',
  - Can cause demotivate others
- Projections are not fact, the reality is more complex

### Foreboding Joy (Brown, 2015)

- Hypervigilance
  - Always on on look out for threats
- Being unable to relax and enjoy life
  - Can lead to burn out.

### Overgeneralising & the myth of self interest (Miller & Ratner, 1998)

- e.g. "people only care about themselves"
- Tend to over-estimate others' self-interest

### Black and White thinking all or nothing thinking

- e.g. "governments are doing nothing"
- reality is more complex and 'greyscale'

### Emotional Reasoning

- e.g. "I am scared of X, that's the risk worst fears often reflect past experiences we can't know for sure what is most likely"

We are all cells in the  
same body of humanity.

Peace Pilgrim

quote fancy

It can also be helpful to prevent overwhelm by retaining a sense of perspective about the individual's role in climate change mitigation and adaptation. While it is true that the actions of one person alone aren't enough to affect the scale of change required, the social comparison effect is bidirectional. Small changes can influence others in, positive ways, making ripples which gather momentum and compound as more and more people join in. No one has to 'save the world' (a very overwhelming responsibility) - we are all responsible for our part.

And if you think that there are too many self-interested people in the world, think again. Miller (1998) has demonstrated the 'Myth of self-interest'. Happily, we tend to overestimate selfish behaviour in others.

Experiments show that just 25% of a group committed to a cause is the tipping point for large scale social change to occur (Centola et al., 2018) [www.ClimatEdPsych.com](http://www.ClimatEdPsych.com)

## 4. Recommendations

Reframe faulty thinking:

- If a pupil (or yourself) has an unhelpful thinking pattern (e.g. nothing I do makes a difference), acknowledge the validity of their concerns then see if you can modify the statement, one step at a time to take reality into account.

e.g my actions have a small influence on others, I might not see how much that is etc...

Stay local and celebrate:

- Focus on community or smaller scale projects
- Highlighting successes in the area or progress you are making will feel more rewarding, achievable and personal to young people, activating a sense of agency and hope

Harness social comparison

- Get talking and organising, knowing that it's all contributing to social change
- 'Be the change' and explain this effect to pupils

Prioritise wellbeing more generally

- Develop a set of wellbeing practices that you like doing. see guide to eco-emotions
- Model, share and practise these with pupils
